INFORMATION ON DEPLETED URANIUM (DU)
A RESOURCE FOR HEALTH CARE PROVIDERS

ADDRESSING YOUR PATIENT’S CONCERNS ABOUT DEPLETED URANIUM
Some Veterans are concerned about the possibility that they were exposed to Depleted Uranium (DU). This fact sheet contains important information for health care providers regarding:

• Assessing the degree of exposure to DU
• Possible health risks from DU exposure
• Resources available to help address Veterans’ and service members’ concerns.

★ WHAT IS DEPLETED URANIUM (DU)?
Uranium is a naturally occurring element that is present in air, water, soil, rocks, plants, and animals

Depleted Uranium (DU) is a by-product of Uranium processing. DU has some of its radioactive component removed during processing. Although it has the same chemical properties as natural uranium, DU is 40% less radioactive than natural uranium.

WHAT ARE THE MILITARY USES OF DEPLETED URANIUM?
DU is a readily available and inexpensive, very strong, heavy metal that has a high melting point. It ignites readily upon friction (pyrophoric) and is highly reactive. All of these properties make DU suitable for use by the US and other militaries to strengthen special armor on tanks and other equipment. DU is currently the most effective metal to use in armor to protect service members. It is also used to harden munitions to penetrate targets better. The first time DU was used by the US military in large quantities was during the Persian Gulf War in the early 1990s. DU weapons and ammunition have also been used in Operation Enduring Freedom (OEF), Operation Iraqi Freedom (OIF), and Operation New Dawn (OND).

HOW ARE SERVICE MEMBERS EXPOSED TO DEPLETED URANIUM?
Exposure to a hazardous substance such as DU requires that (1) there is a source of the material, and (2), that the material is able to get into the body via inhalation, ingestion, skin absorption, and/or tissue penetration.

• Just being in the vicinity of DU tanks or ammunition will not result in exposure or pose a health risk. This is often a key point to make when speaking with Veterans concerned about their possible exposure.

WHAT HAPPENS TO DEPLETED URANIUM ONCE IT’S IN THE BODY?
While very small (microscopic) inhaled DU particles may settle deep in the lungs, larger particles are prevented from getting into the actual lung tissue by the nasopharyngeal filtration system. Those larger particles that are inhaled are then cleared by mucociliary action and swallowed. The DU that is swallowed is excreted in feces without ever being absorbed into the bloodstream. DU shrapnel may become embedded in tissue. This may be removed by surgery, or may need to remain in the body because of its location. The decision to remove or leave the embedded shrapnel is often made by the surgical team(s) that takes care of the injured service member. How long the DU remains in the body depends on where it is or explosions involving DU munitions or armor also had potential exposure to DU.

• When these fires are extremely hot, very fine dust-like DU particles can be created which can then be inhaled into the lungs, swallowed, or may contaminate open wounds. Some of this fine DU dust may settle deep in the lungs and stay there for a long time. If shrapnel which contains DU becomes embedded in tissue, it could also remain in the body for an extended period of time.

For more information, contact  800-248-8005   |   www.WarRelatedIllness.va.gov
located, the DU particle size, how much is present, and how easily the particles dissolve. DU from retained shrapnel is gradually absorbed into the blood stream, then processed by the kidney, and excreted in the urine. This process of absorption and excretion occurs over many years.

**DETERMINING A VETERAN’S LEVEL OF EXPOSURE**

Even though research studies show that service men and women who work around DU will not experience harmful health effects, Veterans may still have concerns. In part, this may be because it is often difficult to figure out whether or not someone had an exposure and if so, the amount of exposure someone may have received. To categorize exposure levels to DU during the Gulf War, the Department of Defense (DoD), and US Army Center for Health Promotion and Preventative Medicine (USACHPPM, now the US Army Public Health Command (USAPHC)) have classified potential exposure and associated risks into three categories. The table below provides some guidance for providers to better determine the probable burden of DU for an individual based on the different types of exposure.

**WHAT ARE THE HEALTH EFFECTS OF DEPLETED URANIUM?**

The possibility of harmful health effects from exposure to DU is based on the amount of DU that stays in the body. Very few service men and women are exposed to a large enough amount of DU or have enough DU left in their body to result in any health effects. Some Veterans worry about DU’s radioactivity, although DU is 40% less radioactive than natural uranium. This has been studied by the World Health Organization, Department of Veterans Affairs (VA), Department of Defense (DoD), the United Kingdom Royal Society, and more recently, the Institute of Medicine (IOM).

Studies on uranium miners and processors (people with high exposure to uranium over a long period of time) have shown that the main short- or long-term health effect of high doses of uranium is a result of it being a heavy metal and its impact on the kidneys. High doses of uranium cause kidney function impairment.

<table>
<thead>
<tr>
<th>QUESTION ABOUT EXPOSURE</th>
<th>POSSIBLE EXPOSURE(S)</th>
<th>CHANCE OF DU IN BODY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Did you have contact with intact DU?</td>
<td>Handling intact DU munitions or sitting inside or near a vehicle with intact DU armor.</td>
<td>The likelihood of exposure is extremely low and would be approximate to zero.</td>
</tr>
<tr>
<td>Did you fire DU munitions?</td>
<td>Loading and firing weapons that fire armor piercing ammunition made of DU. Some smoke/fumes may be present, especially in closed spaces (e.g., tanks).</td>
<td>Quite unlikely that there will be significant body burden of DU.</td>
</tr>
<tr>
<td>Were you in close proximity to burning or exploded DU?</td>
<td>Being in the smoke cloud of exploded DU munitions or burning DU armor, such as on an Abrams battle tank or a Bradley fighting vehicle.</td>
<td>Slight to moderate chance of inhalation and/or ingestion of DU particles.</td>
</tr>
<tr>
<td>Do you have retained DU shrapnel in your body?</td>
<td>Metal fragments from DU armor or DU munitions remain in the body after an attack or accident.</td>
<td>High chance of significant DU in the body. These Veterans may need to be evaluated further for DU exposure or other embedded fragments.</td>
</tr>
</tbody>
</table>
to slowly become worse. Kidney function can be tested easily by blood and urine analyses.

A 2008 study by the IOM included a review of over 1,000 recent research studies which examined exposure to DU and health effects (i.e. cancers and non-malignant diseases, such as neurological problems). The IOM Committee concluded there was not sufficient scientific data to determine whether or not exposure to uranium is associated with any adverse health effects.

The VA and the DoD established the Depleted Uranium Follow-Up Program at the Baltimore VA Medical Center to screen and monitor Veterans for health problems associated with exposure to DU. Since 1993, this program has followed Veterans with retained DU fragments and those exposed to DU as a result of their involvement in “friendly fire” incidents during the Gulf War. After 20 years of follow up, participants with retained DU fragments continue to have elevated urine uranium levels. However, when comparing those with high urine uranium to those with low, there have been no clinically significant differences between those with high and low DU levels. In addition, there has been no link between DU exposure and outcomes such as cancer and birth defects.

The same researchers at the Baltimore VA Medical Center also examined whether or not breathing in DU containing smoke/dust during friendly fire incidents affected the lungs. There was no evidence of abnormal breathing tests or lung disease in persons who had such exposures.

TALKING ABOUT THE RISKS OF DU EXPOSURE WITH A PATIENT
How you speak with your patient about possible exposure and health risks from DU is as critical as the scientific and medical information you share. The field of risk communication provides some guidance about how to discuss environmental health risks. Among the most critical components are TRUST and CREDIBILITY of the source of information which includes you as the provider. These characteristics are often judged in the first moments of the initial interaction. Being honest and open with the Veteran about what you do and do not know is important and can set the stage for a meaningful dialogue.

Two strategies to increase trust and credibility are demonstrating that you are LISTENING and EMPATHIZING or acknowledging their concern. For example, you can demonstrate listening by reflecting back or paraphrasing what the patient is telling you- “It sounds like you’re concerned about your exposure to depleted uranium because of its radioactivity… let me tell you what we know about that.”

Allow the patient to completely state his or her concerns before attempting to provide factual information. This will allow you to tailor the information you have to that individual’s need and gauge the extent of concern. After you have a sense of this, offer to read through the patient education sheet about DU with him or her. Together, you can assess the probable level of exposure to DU and decide on a plan of action.

WHAT IS THE ‘TEST’ FOR DU AND WHAT DOES IT SHOW?
There is a 24-hour urine collection test that measures the total uranium excreted in the urine, the so-called excretion rate. If the sample has enough total uranium content, an additional test is performed on the same urine sample to determine if the uranium is from natural sources or if it is DU. All urine samples are sent to and processed by the Baltimore VA Medical Center. (For more details, contact your local Environmental Health Coordinator or visit this link: http://www.publichealth.va.gov/exposures/depleted_uranium/followup_program.asp.) Results will show the level of total uranium in the urine compared to the normal range of excretion in the general public and indicate if the source is natural or DU. While other tests are occasionally used, the 24-hour urinary excretion rate is considered the “gold standard”.

All Veterans of GW1, OEF, OIF, and OND are eligible to have the 24-hour urine collection test performed at no cost to them. The results of the test
for uranium will be communicated
directly to the Veteran by letter.
A copy is sent to the referring VA
provider, as well. It is important to
know that the test does not measure
any impact on kidney function
or any health effect of the DU. If
the result indicates DU exposure,
the patient may be enrolled in an
ongoing program to follow the
uranium excretion rate over time. This
determination will be made based on
discussions among the Veteran, his or
her VA primary care provider, and the
staff at the Baltimore DU Follow-up
Program.

WHEN SHOULD A VETERAN BE
REFERRED TO THE WRIISC?

If you see a Veteran with DU exposure
concerns that you cannot address
(or any chronic symptoms that defy
diagnosis after standard work up),
you can consider sending him or her
to the WRIISC. Our comprehensive
evaluation includes an environmental
and occupational exposure
evaluation or you can request this as a
stand-alone service. To refer Veterans
to the WRIISC you can simply enter
an Interfacility Consult by visiting our
Web site at:

or call the WRIISC location nearest
you:

• East Orange, NJ: 1-800-248-8005
• Palo Alto, CA: 1-888-482-4376
• Washington, DC: 1-800-722-8340.
